## Sage Hill

Coastal sage scrub (CSS) ecosystems in Southern California are under serious threat due to disturbance, development, and invasive species.

On the UCLA campus, there are four acres of undeveloped CSS called Sage Hill. This space has been recently disturbed.

**Question:** How can we best restore the ecosystem and ecosystem function on Sage Hill?

## Objectives

Our goal was to test a proof of concept of CSS ecosystem restoration.

- Test different assemblages of California natives and invasive plant removal
- Observe effects on:

Plant Growth and Survival

Invertebrate Community

Soil Characteristics

## Plant Assemblages

### Native Mix

California sage  
*Artemisia californica*

Monkey flower  
*Mimulus aurantiacus*

Woolly blue curls  
*Trichostema lanatum*

Bush sunflower  
*Encelia californica*

### Native Sages

California sage  
*Artemisia californica*

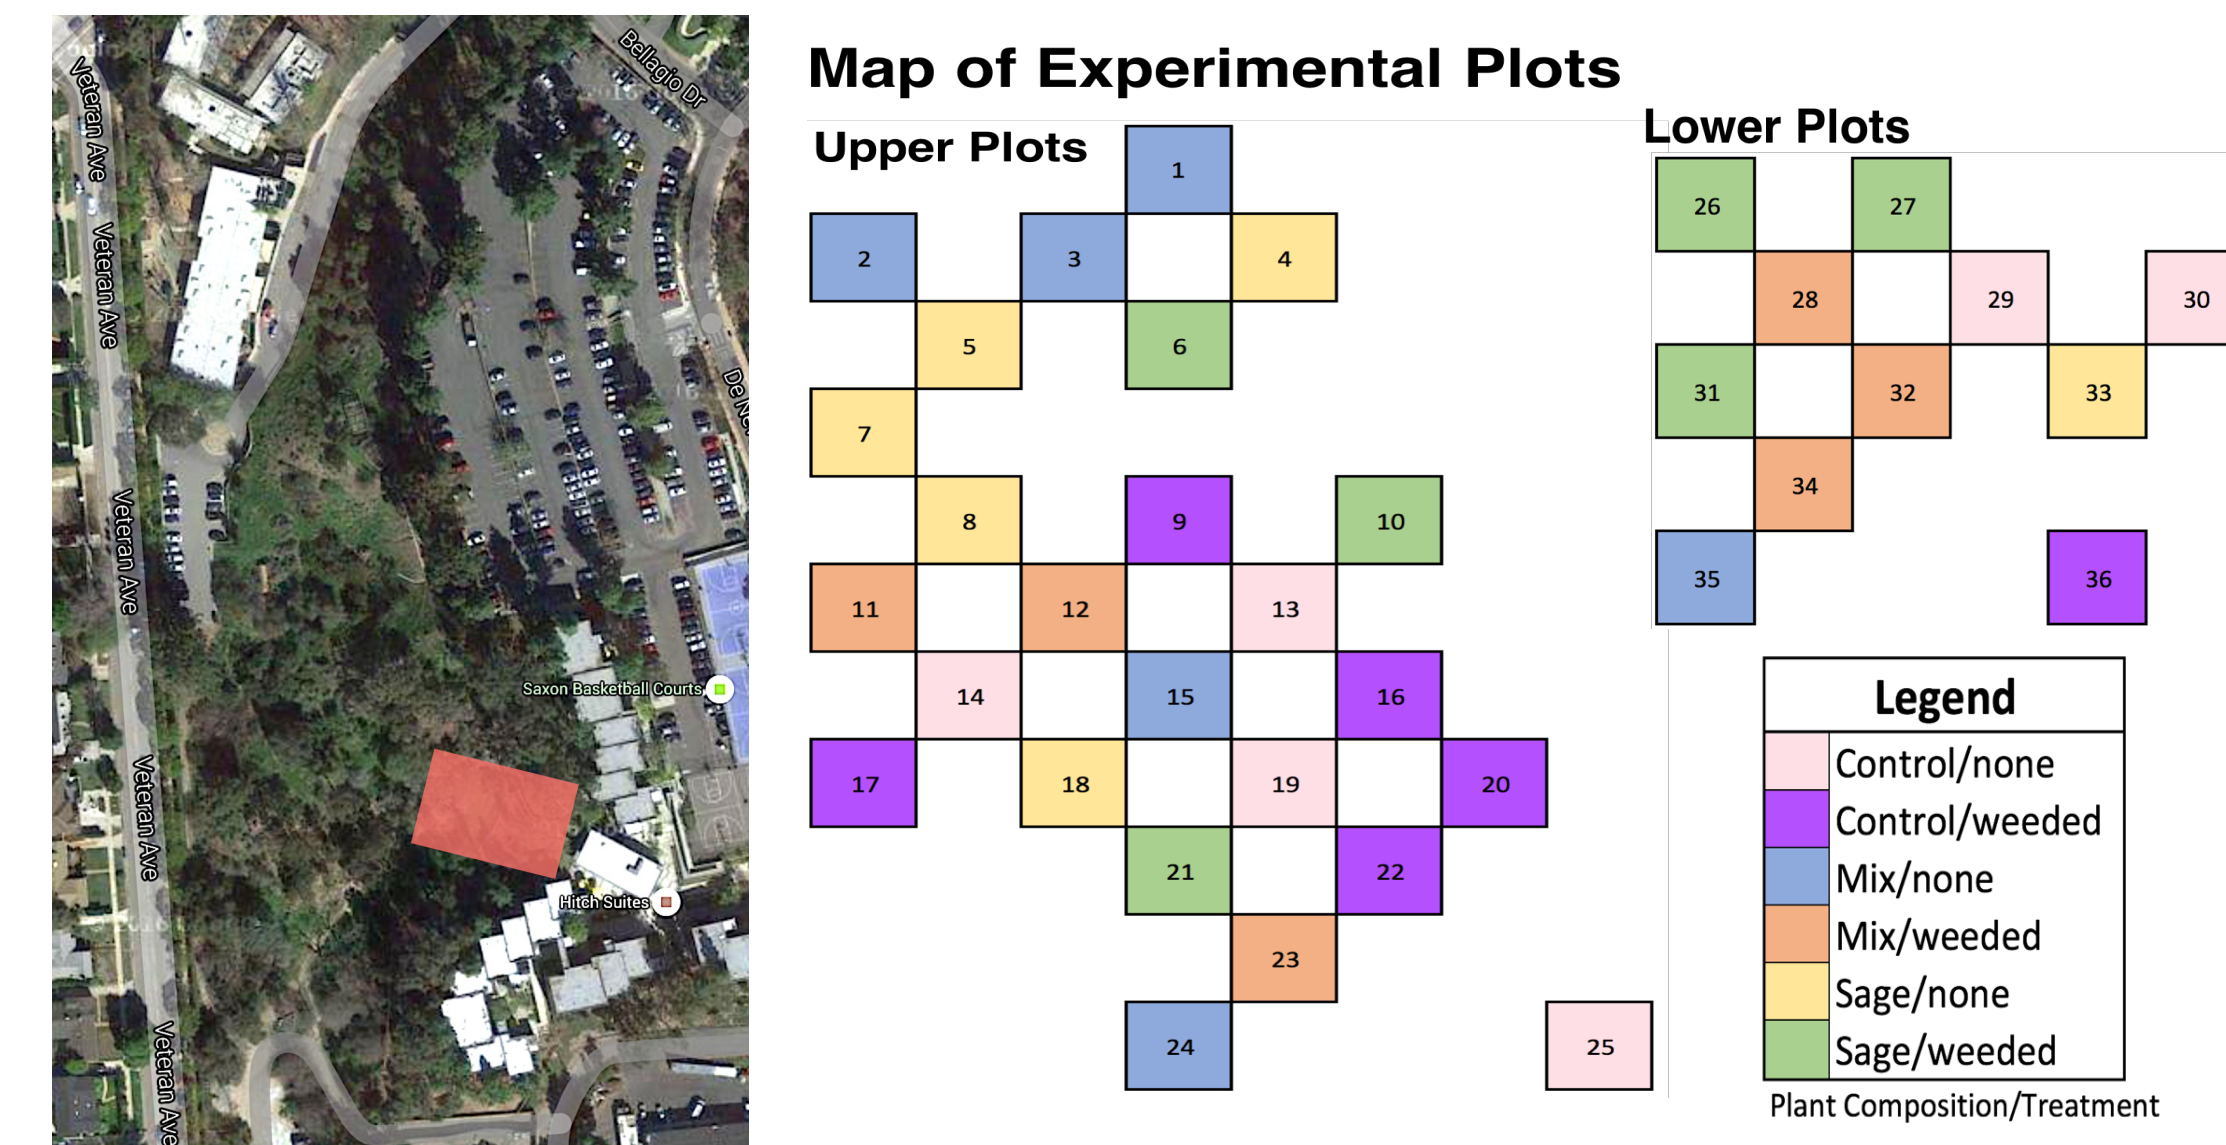

White sage  
*Salvia apiana*

Purple sage  
*Salvia leucophylla*

## Experimental Design

36 one-meter<sup>2</sup> plots in a checkerboard pattern

Treatments were randomly assigned to plots. There were 6 replicates of each treatment:

1. Native Sage Weeded
2. Native Sage Non-weeded
3. Native Mix Weeded
4. Native Mix Non-weeded
5. Control (No plants) Weeded
6. Control (No plants) Non-Weeded

## Methods

### Soil samples\*:

- 0cm and 15 cm depth
- Samples dried in oven and calculated soil moisture.

### Invertebrate samples\*:

- Pitfall traps in the center of each plot
- Measured abundance and species richness

\*before and after experiment

### Weekly Plant Measurements

- Stem length
- Individual survival

Two-sampled t-tests run in JMP 12.1

## Results

### Soil

- Preliminary samples showed no difference between plots.
- **Difference in soil moisture between weeded and non-weeded plots (P<0.001).**
- No difference between plant compositions.

### Invertebrates

#### Species Richness

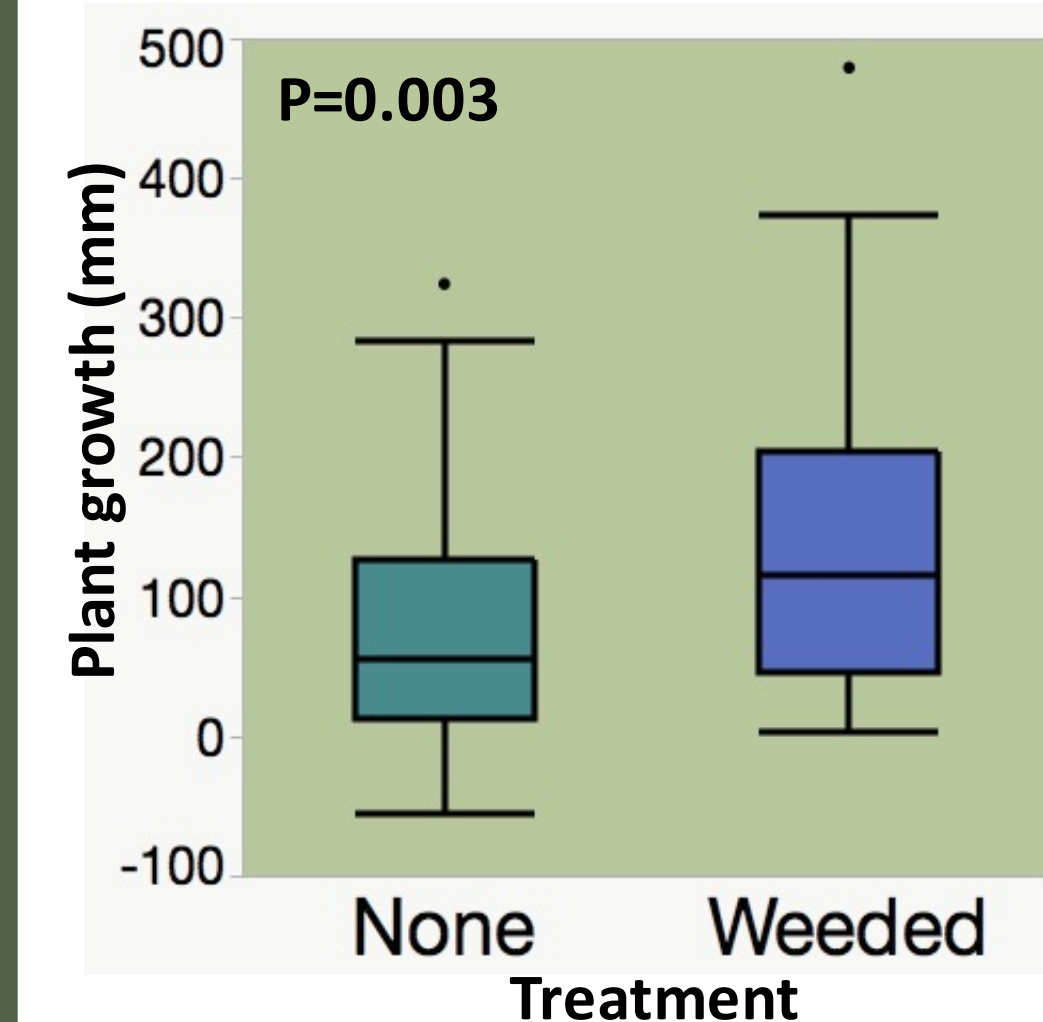

- Difference between species richness **before and after experiment (P=0.003).**
- No difference between richness or abundance between the weeding treatments or plant compositions (P>0.050).

#### Invertebrate Community Before and After Experiment

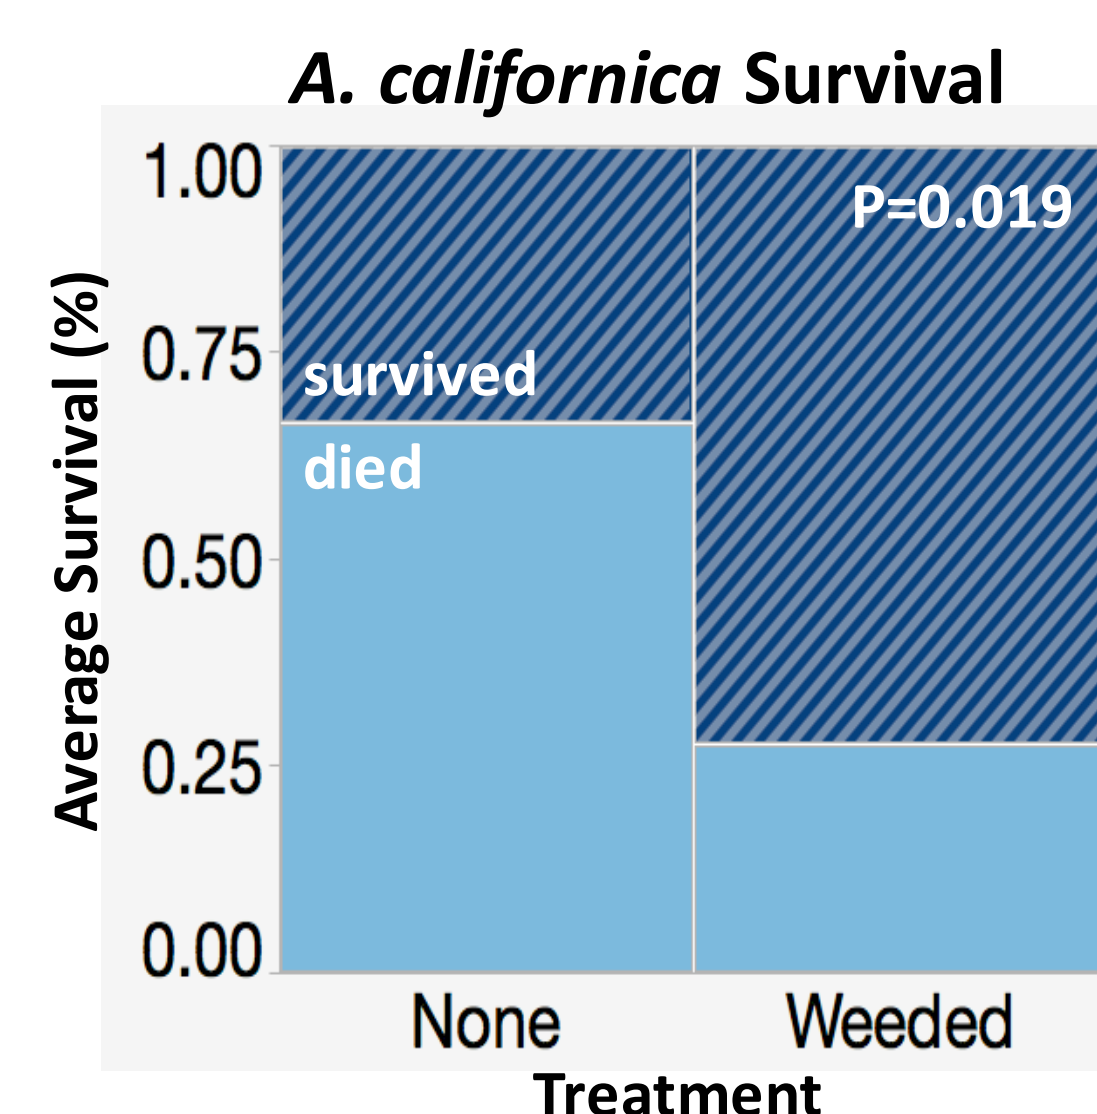

Common Name	Family	PRE	POST
Pincer Bug	Dermoptera	X	X
Ant	Formicidae	X	X
Aphid	Aphididae	X	X
Spider Mites	Tetranychidae	X	
Ladybug	Coccinellidae		X
Bee	Apidae		X
Jerusalem Cricket	Stenopelmatidae		X

### Plants

#### Growth Between Treatments

- Difference in **growth** with weeding (P=0.003).
- Difference in **survival** with weeding (P=0.042).
- Difference in ***A. californica* survival** with weeding (P=0.019).

## Conclusions

**Weeding had the greatest impact on changes in ecosystem characteristics.**

- *Soil* moisture increased
- *Plant* survival increased

### Possible Seasonality Effect

- *Invertebrate* community change

### Future Management and Study:

- Focus on invasive management for future restoration work
- Research other combinations of plants
- Expansion to other levels of biodiversity
- Longer studies

## Acknowledgements

We thank Dr. Thomas Gillespie, Kebonye Dintwe, Thomas Huggins, and Phil Rundel for their guidance in this work. We also thank UCLA Library for the UCLA Library Poster Grant. Finally, we thank the many volunteers who helped us with planting and gathering data. This project is part of Sustainable Action Research in the Institute of the Environment and Sustainability.
